Statistics 120
Pie Charts, Bar Charts & Dot Charts

Customizing Pie Chart Colours

Different colours can be specified for the pie slices with a `col=` argument. For example:

```
> pie(meat,
      main = "New Zealand Meat Consumption",
      col = hcl(seq(0, 240, by = 60)))
```

## A Single Categorical Variable

- We often need to display a set of values each of which is associated with a single category of a factor or ordered factor.

- Most commonly the values are counts or proportions.

- Here is a typical example.

New Zealand Meat Consumption (1997)

Lamb	Mutton	Pigmeat	Poultry	Beef
8%	10%	16%	25%	41%

- Proportions are often presented in pie charts.

New Zealand Meat Consumption
Producing a Pie Chart with R

A basic pie chart is produced from a vector of named values. such a vector can be created as follows:

```
> meat = c(8, 10, 16, 25, 41)
> names(meat) = c("Lamb", "Mutton", "Pigmeat",
                   "Poultry", "Beef")
```

Once the data vector is created, the plot is easy to create.

```
> pie(meat,
      main = "New Zealand Meat Consumption")
```

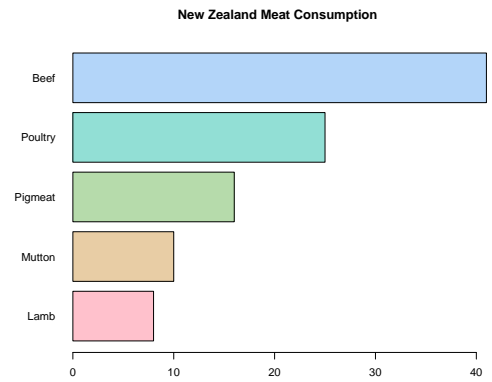

Pie Charts

- Perceptual theory suggests that pie charts are not a good way of presenting information because they are based on angles or areas.

- Often pie charts are presented with the values as part of or close to the pie slice labels. This indicates that it is hard to decode the encoded values.

- Pie charts are only useful for proportions. They can't be used for other kinds of values.

New Zealand Meat Consumption
Bar Charts

- Bar charts provide a useful alternative way of presenting a set of values associated with the levels of a factor.

- Bar charts can be used for values other than proportions.

- Bar charts use position on a common scale to encode their values.

- This means they provide a better way of delivering information than pie charts.

New Zealand Meat Consumption

(bar chart: Lamb ~8, Mutton ~10, Pigmeat ~16, Poultry ~25, Beef ~41)

New Zealand Meat Consumption

(horizontal bar chart: Beef ~41, Poultry ~25, Pigmeat ~16, Mutton ~10, Lamb ~8)

Producing a Bar Chart with R

A basic bar chart is produced as follows:

```
> barplot(meat, col = "lightblue",
          main = "New Zealand Meat Consumption")
```

In pie charts it is very important to colour the slices different colours. In bar charts it is less important, but it can still be done.
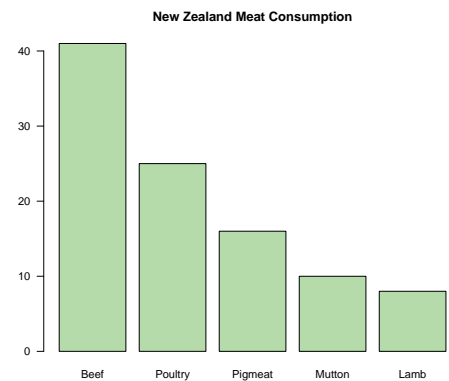

```
> barplot(meat,
          main = "New Zealand Meat Consumption",
          col = hcl(h = seq(0, 240, by = 60)),
          las = 1)
```

(Note the use of `las=1` here to rotate the *y* axis labels.)

Pareto Charts

- Pareto charts are a bar plot variation which are used in quality control work.

- A Pareto chart sorts the bars of a barplot from biggest to smallest, left to right across the graphs.

- They are typically used to determine an importance ordering of faults detected in a manufacturing process.

- Pareto charts can be produced in R using the function `sort`.

  ```
  > barplot(sort(meat, decreasing = TRUE),
        main = "New Zealand Meat Consumption",
        col = hcl(120), las = 1)
  ```

New Zealand Meat Consumption

(bar chart: Lamb ~8, Mutton ~10, Pigmeat ~16, Poultry ~25, Beef ~41)

New Zealand Meat Consumption

(bar chart: Beef ~41, Poultry ~25, Pigmeat ~16, Mutton ~10, Lamb ~8)

Horizontal Bars

It can be useful to draw the bars of bar-chart horizontally. In R, this is done by specifying `horiz=TRUE`.

```
> barplot(meat,
          main = "New Zealand Meat Consumption",
          col = hcl(seq(0, 240, by = 60)),
          horiz = TRUE,
          las = 1)
```

Dot Charts

- Dot charts are very similar to a horizontal bar chart.

- The bars are replaced by a single "dot" and a horizontal grid line.

- Dot charts have the advantage that many more bars can be plotted horizontally.

- In R, dotcharts are easy to produce.

  ```
  > dotchart(meat,
        main = "New Zealand Meat Consumption",
        xlab = "Percentage")
  ```

New Zealand Meat Consumption
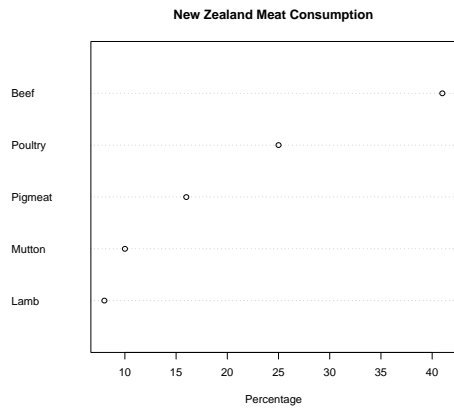

Two Category Bar Charts

Here is a set of data which is *cross-classified* by two factors.

**Percentage of the New Zealand Population
With a Potentially Hazardous Drinking Pattern**

		Age		
Sex	*15-24*	*25-44*	*45-64*	*65+*
Male	41	28	21	9
Female	26	9	4	.5

This is exactly the form of data produced by `table`.
It is also possible to input this data directly as a matrix.

Improving the Default Layout

- There are clear problems with default barplot.

- The colours are awful!

- The plot needs a *legend* explaining what the two colours mean.

- The plot needs an overall title and labels for the *x* and *y* axes.

- The tick mark labels should be horizontal.

- The tick marks should span the full height of the bars.

Data for Two Category Bar Charts

```
> alcohol = matrix(c(41, 26,
      28, 9, 21, 4, 9, 0.5),
      nr = 2)
> dimnames(alcohol) = list(Sex = c("Male",
      "Female"), Age = c("15-24",
      "25-44", "45-64", "65+"))
> alcohol
        Age
Sex     15-24 25-44 45-64 65+
  Male     41    28    21 9.0
  Female   26     9     4 0.5
```

This is a 2×4 matrix with row and column labels.

Improving the Default Layout

```
> main = c("Potentially Hazardous Drinking Patterns",
        "In The New Zealand Population")

> barplot(alcohol,
        legend = rownames(alcohol),
        col = hcl(c(240, 120)),
        ylim = c(0, 70),
        las = 1,
        main = main,
        xlab = "Age Group",
        ylab ="Percentage")
```

The legend could also be added with a separate `legend`
statement. This is more flexible.

Bar Chart Layout

There are two ways in which a barchart for cross-classified variables can be produced:

- stacked bars.

- side-by-side bars.

Both of these layouts are possible in R.

The simplest bar chart command is:
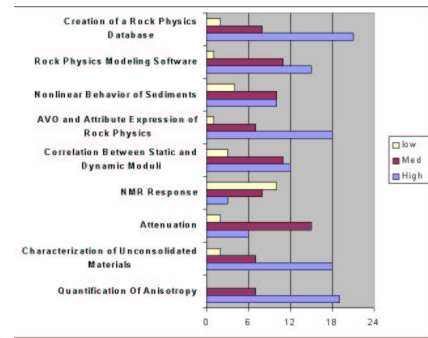

```
> barplot(alcohol)
```

Side-by-Side Bars

Instead of drawing the "stacked" form of bar chart, it is also possible to produce a "side-by-side" form.
```
> barplot(alcohol, beside = TRUE,
        legend = rownames(alcohol),
        col = hcl(c(240, 120)),
        ylim = c(0, 50),
        las = 1,
        main = main,
        xlab = "Age Group",
        ylab ="Percentage")
```

Student Rankings

This is the basic bar chart produced by Excel.

Gradient Background. Three dimensional bars.

Choosing a Layout

- The side-by-side bar plot variant encodes all its values as positions on a common scale (i.e. the position of the top of bar).

- The stacked bar plot variant encodes some of its information in the lengths of the stacked bars.

- Perceptual theory tells us that the side-by-side version will work best.

- Occasionally the stacked version is useful — this is when the combined height of the bars is meaningful.

Tourism-Related Gross Receipts/Sales
1996-2000 in Billions
Gross sales generated by the Minnesota tourism industry grew 31% from 1996 to 2000. Adjusted for inflation, this represents a real average annual growth rate of almost 4%.

Some Examples

- There are thousands of examples of bar charts on the Web.

- To see a sample of them go to Google Images and search for "bar chart."

- Here a few examples.
