

Chapter 4: Mathematical Induction

So far in this course, we have seen some techniques for dealing with stochastic processes: first-step analysis for hitting probabilities (Chapter 2), and first-step analysis for expected reaching times (Chapter 3). We now look at another tool that is often useful for exploring properties of stochastic processes:

4.1 Proving things in mathematics

There are many different ways of constructing a formal proof in mathematics. Some examples are:

- Proof by counterexample: a proposition is proved to be *not generally true* because a *particular example* is found for which it is not true.
- **Proof by contradiction:** this can be used either to prove a proposition is true or to prove that it is false. To prove that the proposition is true (say), we start by assuming that it is false. We then explore the consequences of this assumption until we reach a contradiction, e.g. 0 = 1. Therefore something must have gone wrong, and the only thing we weren't sure about was our initial assumption that the proposition is false so our initial assumption must be wrong and the proposition is proved true.

A famous proof of this sort is the proof that there are infinitely many prime numbers. We start by assuming that there are finitely many primes, so they can be listed as p_1, p_2, \ldots, p_n , where p_n is the largest prime number. But then the number $p_1 \times p_2 \times \ldots \times p_n + 1$ must also be prime, because it is not divisible by any of the smaller primes. Furthermore this number is definitely bigger than p_n . So we have contradicted the idea that there was a 'biggest' prime called p_n , and therefore there are infinitely many primes.

• **Proof by mathematical induction:** in mathematical induction, we start with a formula that we *suspect* is true. For example, I might *suspect* from

observation that $\sum_{k=1}^{n} k = n(n+1)/2$. I might have tested this formula for many different values of n, but of course I can never test it for *all* values of n. Therefore I need to prove that the formula is *always* true.

The idea of mathematical induction is to say: *suppose* the formula is true for all n up to the value n = 10 (say). Can I prove that, if it is true for n = 10, then it will also be true for n = 11? And if it is true for n = 11, then it will also be true for n = 12? And so on.

In practice, we usually start lower than n = 10. We usually take the very easiest case, n = 1, and prove that the formula is true for n = 1: LHS = $\sum_{k=1}^{1} k = 1 = 1 \times 2/2 = \text{RHS}$. Then we prove that, if the formula is ever true for n = x, then it will always be true for n = x + 1. Because it is true for n = 1, it must be true for n = 2; and because it is true for n = 2, it must be true for n = 3; and so on, for all possible n. Thus the formula is proved.

Mathematical induction is therefore a bit like a

The method of mathematical induction for proving results is very important in the study of Stochastic Processes. This is because a stochastic process builds up one step at a time, and mathematical induction works on the same principle.

Example: We have already seen examples of inductive-type reasoning in this course. For example, in Chapter 2 for the Gambler's Ruin problem, using the method of repeated substitution to solve for $p_x = \mathbb{P}(\text{Ruin} \mid \text{start with } \$x)$, we discovered that:

- $p_2 = 2p_1 1$
- $p_3 = 3p_1 2$
- $p_4 = 4p_1 3$

We deduced that

To prove this properly, we should have used the method of mathematical induction.

4.2 Mathematical Induction by example

This example explains the style and steps needed for a proof by induction.

Question: Prove by induction that
$$\sum_{k=1}^{n} k = \frac{n(n+1)}{2}$$
 for any integer n .

Approach: follow the steps below.

(i) First verify that the formula is true for a *base case*: usually the smallest appropriate value of n (e.g. n=0 or n=1). Here, the smallest possible value of n is n=1, because we can't have $\sum_{k=1}^{0}$.

(ii) Next suppose that formula (\star) is true for all values of n up to and including some value x. (We have already established that this is the case for x=1). Using the hypothesis that (\star) is true for all values of n up to and including x, prove that it is therefore true for the value n=x+1.

(iii) Refer back to the base case: if it is true for n=1, then it is true for n=1+1=2 by (ii). If it is true for n=2, it is true for n=2+1=3 by (ii). We could go on forever. This proves that the formula (\star) is true for all n.

General procedure for proof by induction

The procedure above is quite standard. The inductive proof can be summarized like this:

Question: prove that f(n) = g(n) for all integers $n \ge 1$.

Base case: n = 1. Prove that f(1) = g(1) using

$$LHS = f(1)$$

$$= \vdots$$

$$= g(1) = RHS.$$

General case: suppose the formula is true for n = x: so f(x) = g(x). Prove that the formula is therefore true for n = x + 1:

LHS =
$$f(x+1)$$

= $\begin{cases} \text{some expression breaking down } f(x+1) \\ \text{into } f(x) \text{ and an extra term in } x+1 \end{cases}$
= $\begin{cases} \text{formula is true for } n=x, \text{ so substitute} \\ f(x)=g(x) \text{ in the line above} \end{cases}$
= $\{\text{do some working}\}$
= $g(x+1)$
= RHS .

Conclude: the formula is true for n=1, so it is true for n=2, n=3, $n=4,\ldots$

It is therefore true for all integers $n \geq 1$.

4.3 Some harder examples of mathematical induction

Induction problems in stochastic processes are often trickier than usual. Here are some possibilities:

- Backwards induction: start with base case n = N and go backwards, instead of starting at base case n = 1 and going forwards.
- Two-step induction, where the proof for n = x + 1 relies not only on the formula being true for n = x, but also on it being true for n = x 1.

The first example below is hard probably because it is too easy. The second example is an example of a two-step induction.

Example 1: Suppose that $p_0 = 1$ and $p_x = \alpha p_{x+1}$ for all $x = 1, 2, \ldots$ Prove by mathematical induction that $p_n = 1/\alpha^n$ for $n = 0, 1, 2, \ldots$

Example 2: Gambler's Ruin. In the Gambler's Ruin problem in Section 2.7, we have the following situation:

- $p_x = \mathbb{P}(\text{Ruin} | \text{start with } \$x);$
- We know from first-step analysis that $p_{x+1} = 2p_x p_{x-1}$ (G₁)
- We know from common sense that $p_0 = 1$ (G_2)
- By direct substitution into (G_1) , we obtain:

$$p_2 = 2p_1 - 1 p_3 = 3p_1 - 2$$

• We develop a suspicion that for all $x = 1, 2, 3, \ldots$,

$$p_x = xp_1 - (x-1) \qquad (\star)$$

• We wish to prove (\star) by mathematical induction.

For this example,
