Island Restoration

- Ecosystems are complex and most components, particularly cryptic, small and microbial, remain undiscovered
- Methods are needed for rapidly collecting data to set restoration targets and monitor whole-ecosystem recovery following conservation interventions
- Advances in molecular tools, particularly next-generation sequencing, are a powerful framework
 - characterise ecosystems by species bar-coding
 - phylogeography and species-abundance

A Model Ecosystem

- We established a **pilot** project to test the feasibility of phylogenetically and environmentally characterizing every species in a well-defined New Zealand island ecosystem using modern sequencing, informatics and biogeography **CURRENT STATUS**
- We then can investigate important ecological questions from conservation (eradication recovery, climate change) to theoretical (unified neutral theory of biogeography and biodiversity) over time and space

Te Hauturu-o-Toi (Little Barrier I.)

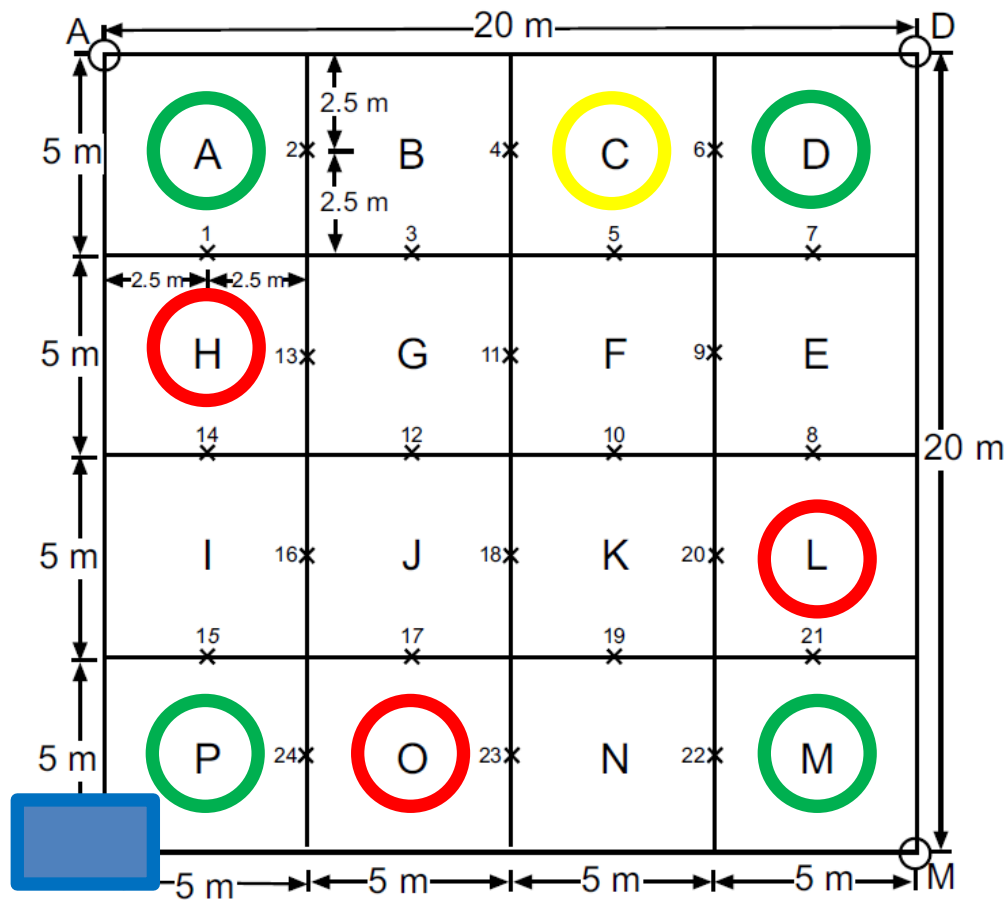

- 2,817 hectares
- 25 km offshore
- Nature Reserve (1895)
- Post-eradication recovery

Sampling Strategy

- Ten sampling sites on an elevational gradient

Molecular Tools

- c850 vascular plants sequenced for eight loci
 - chloroplastic: *rbcL*, *matK*, *rpoC1*, *trnL*, *trnL-F*, *psbA-trnH*, nuclear ITS, and mitochondrial *nad5*
- c1200 invertebrates sequenced
 - non-destructive DNA extraction
 - cytochrome oxidase 1 (CO1)
- Avian sequences from reference database
 - cytochrome oxidase 1 (CO1)

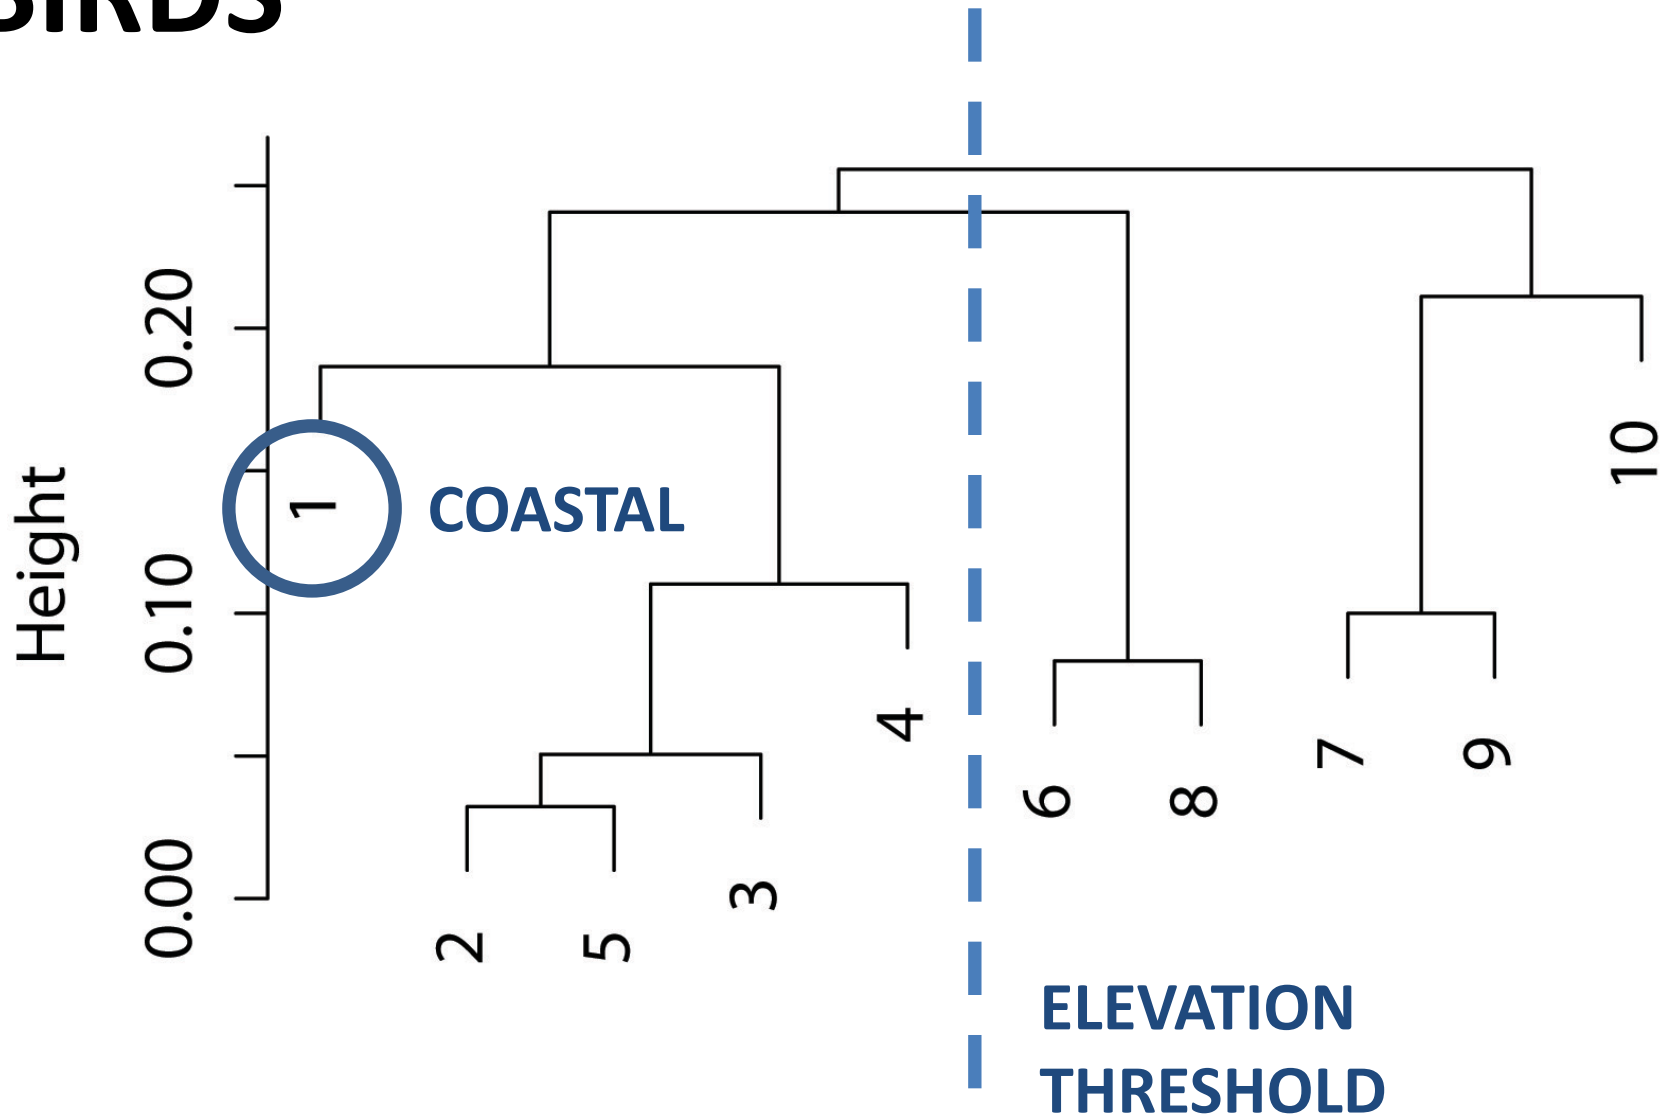

Operational Taxonomic Units

- For the pilot study we grouped operational taxonomic units (OTUs) for invertebrates
 - OTU <1% genetic divergence (529 => 212)
- Ultimately use shared phylogenetic diversity

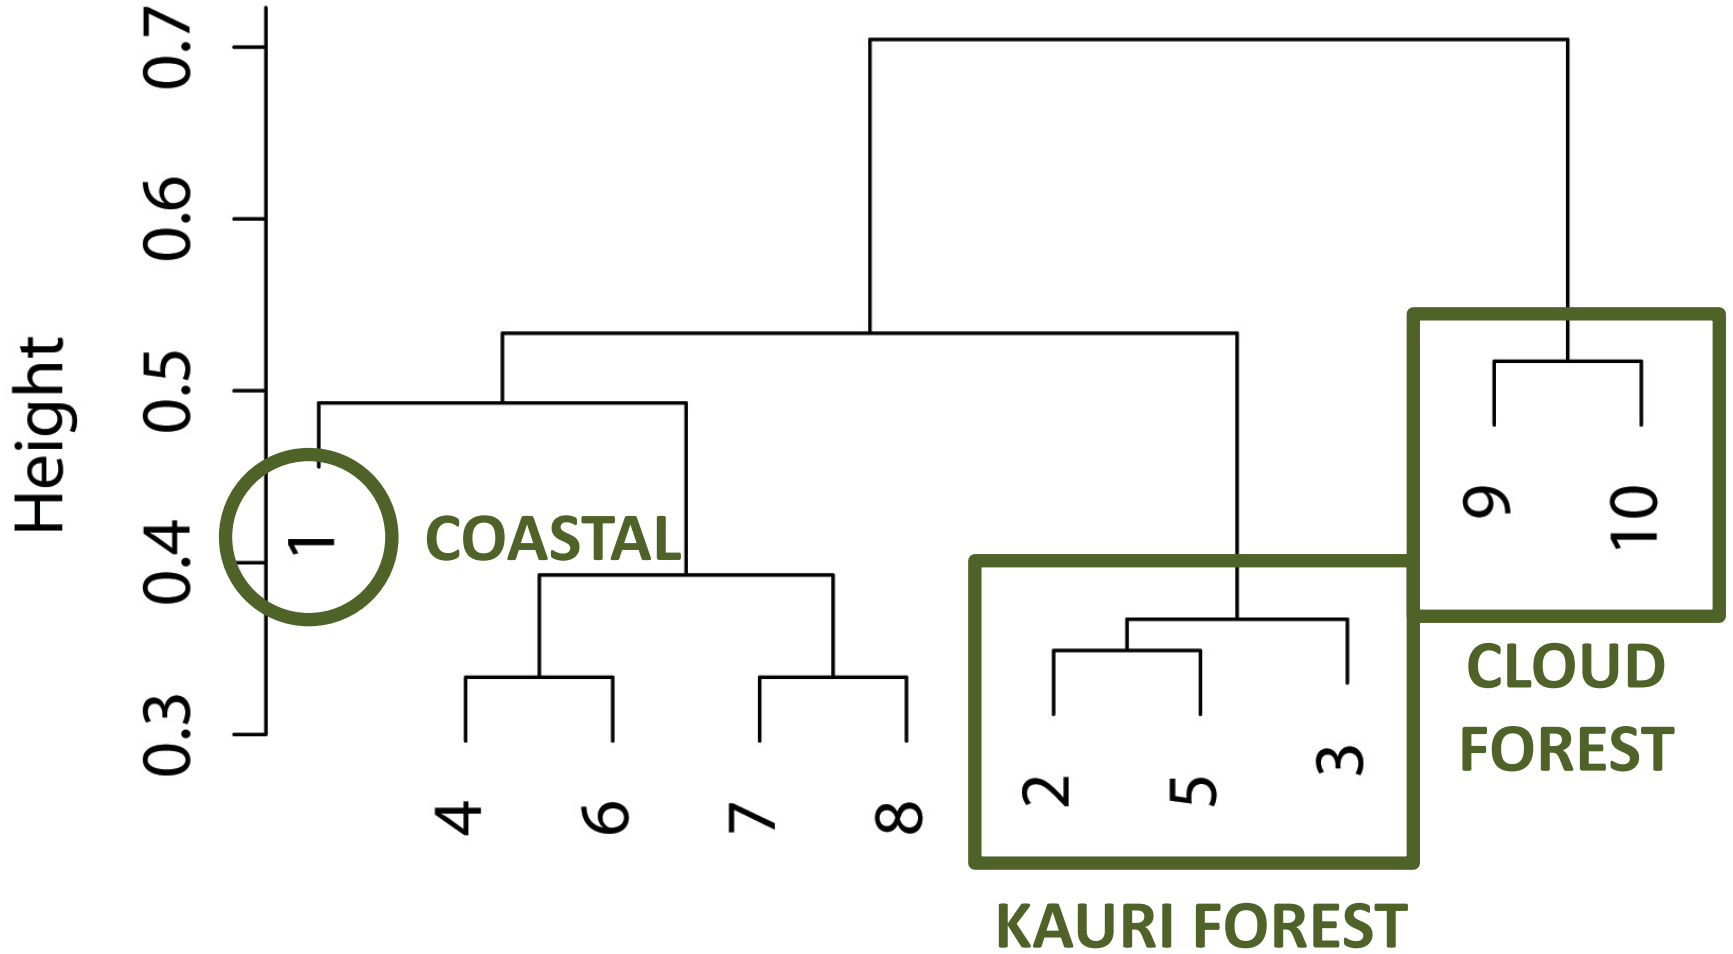

BIRDS

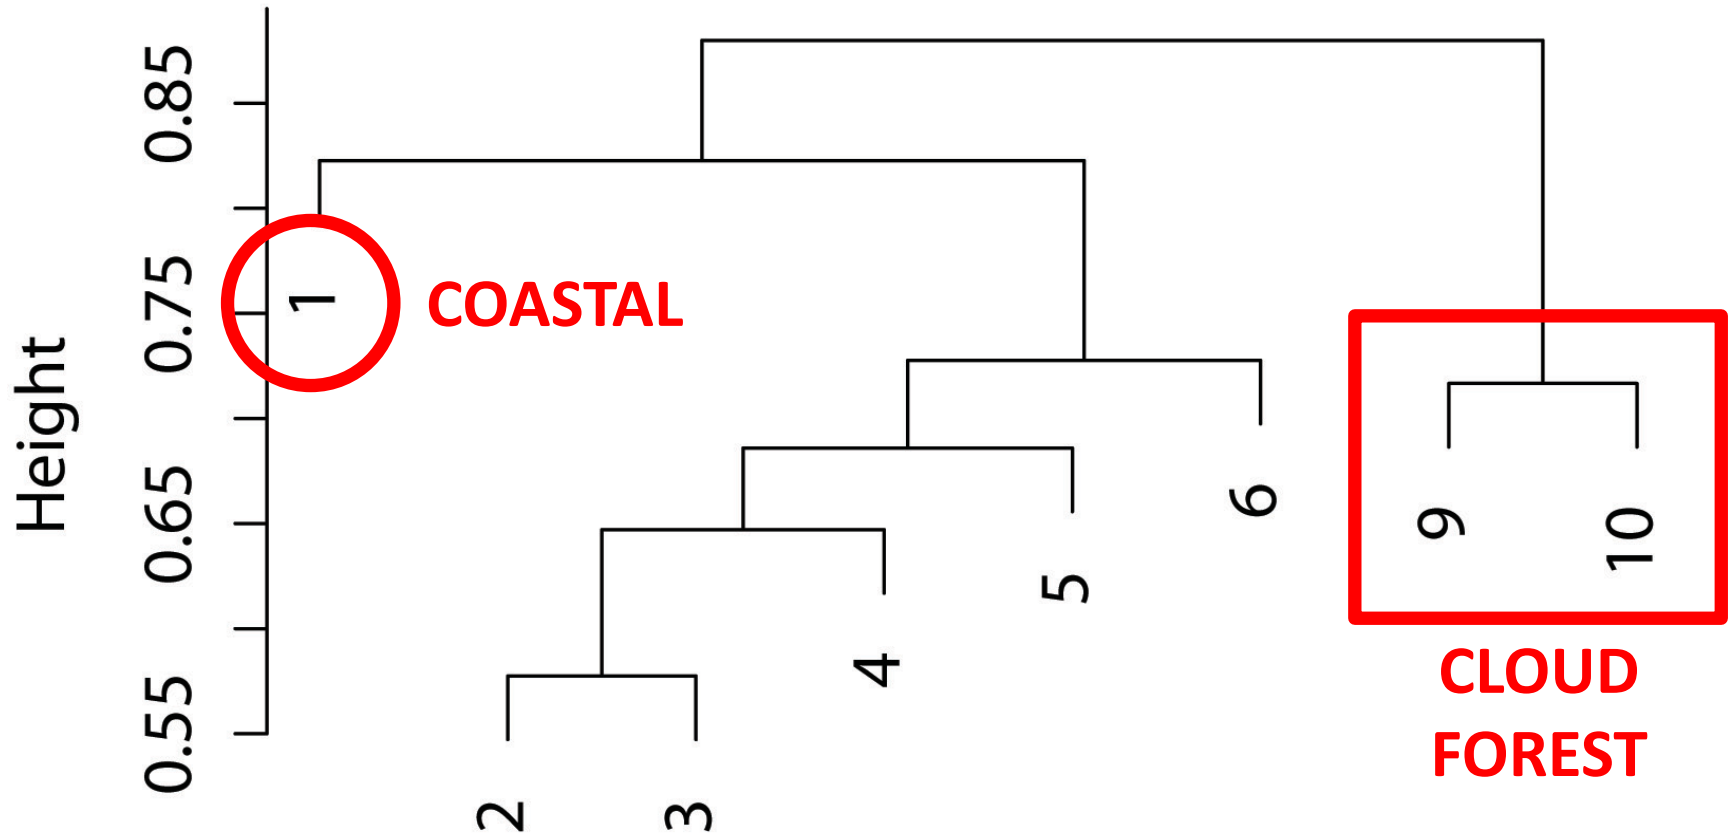

Elevation (m)
Agglomerative Coefficient = 0.61

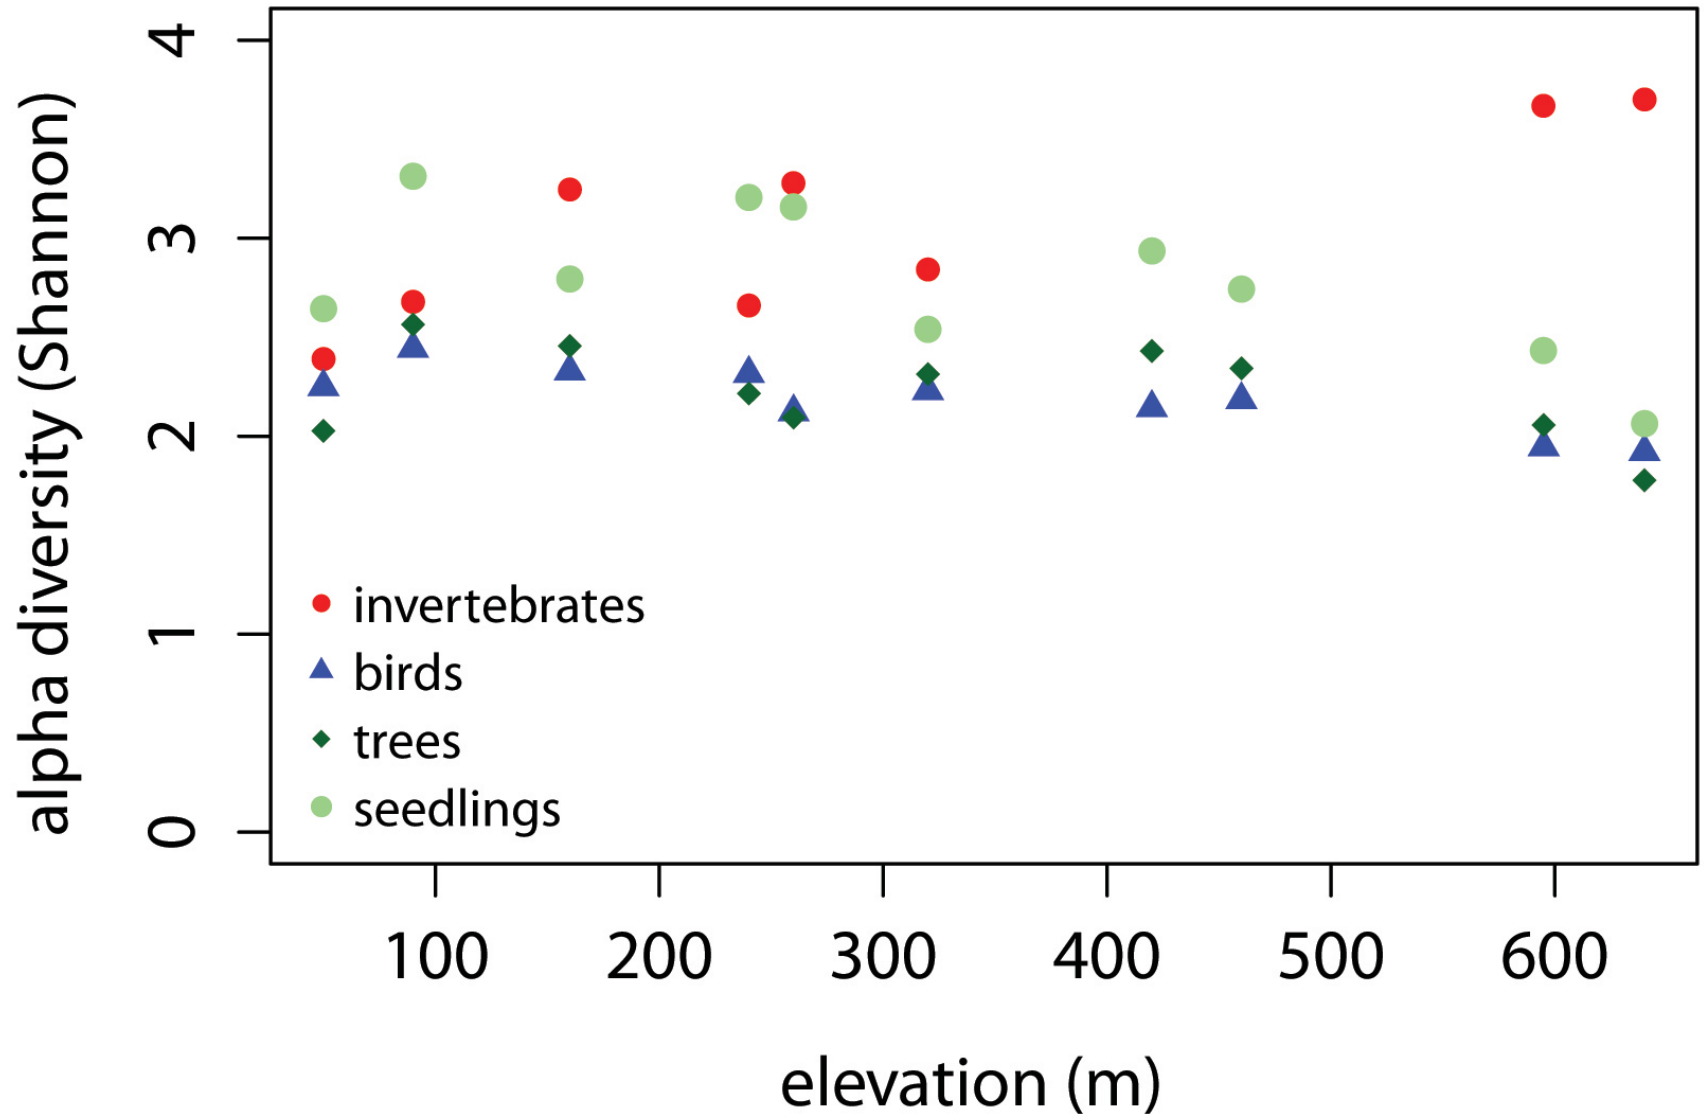

TREES

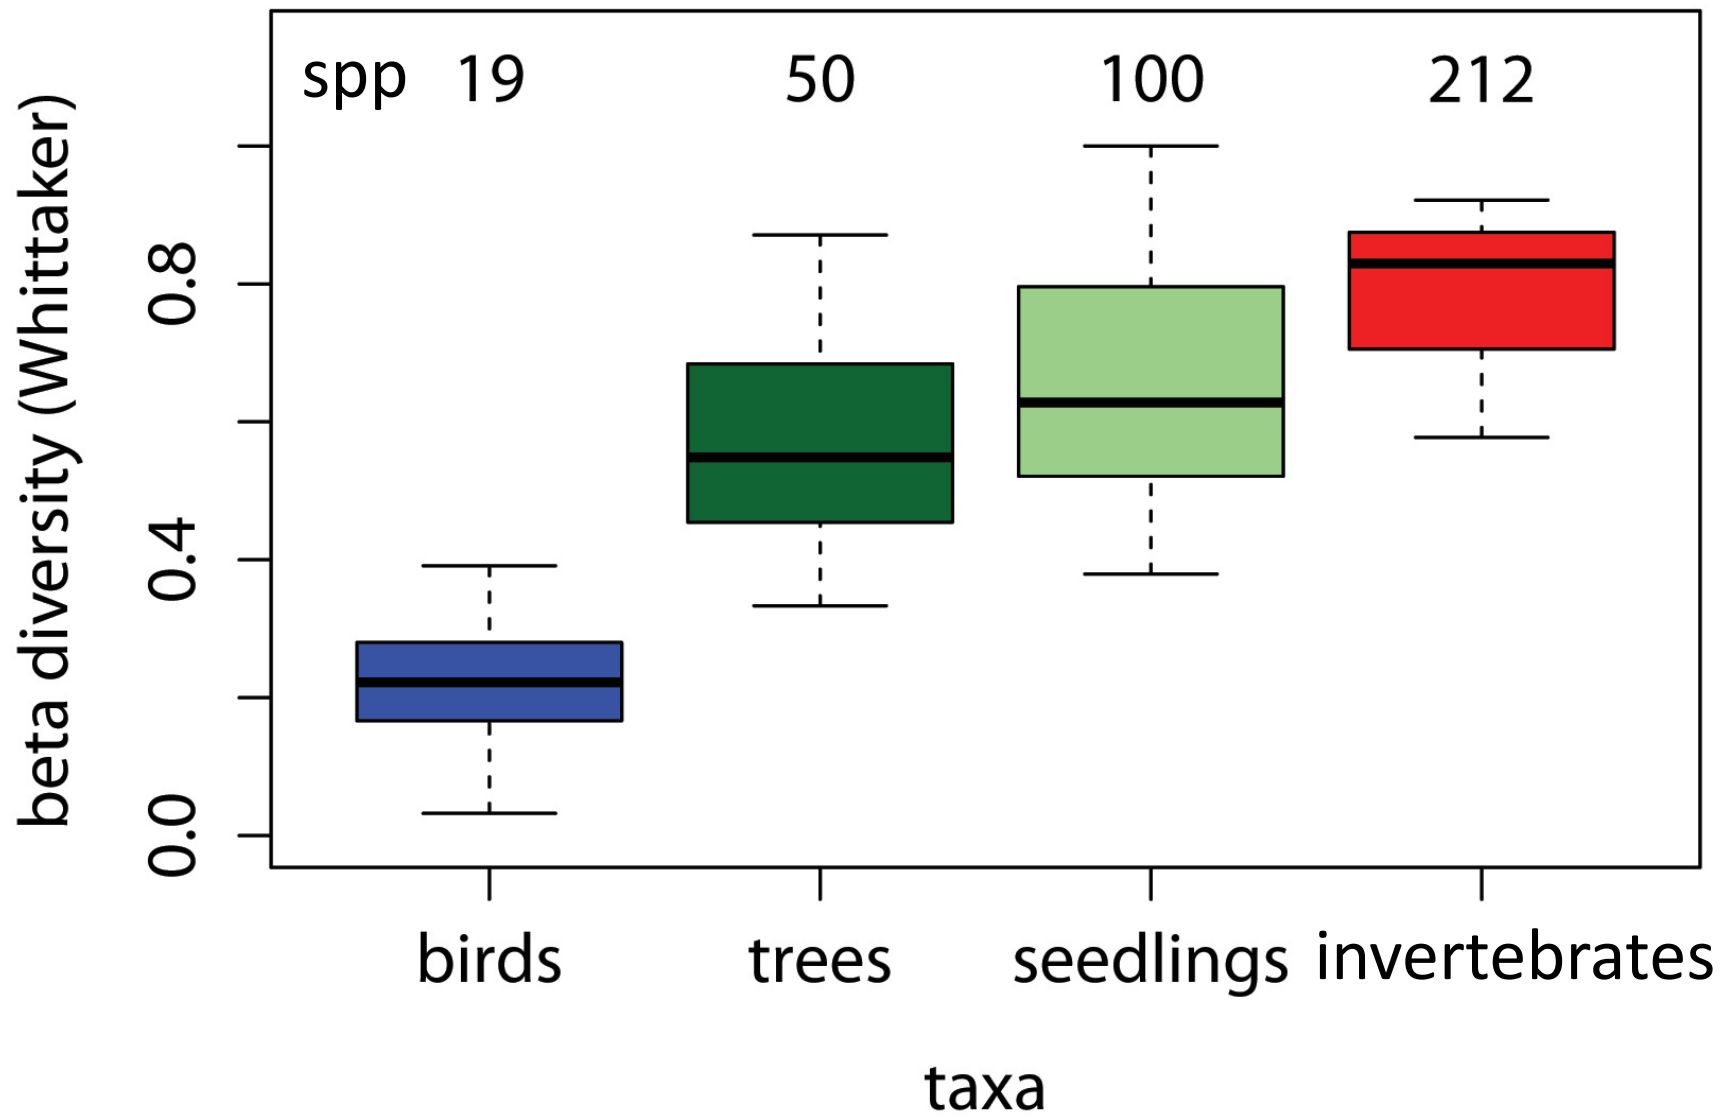

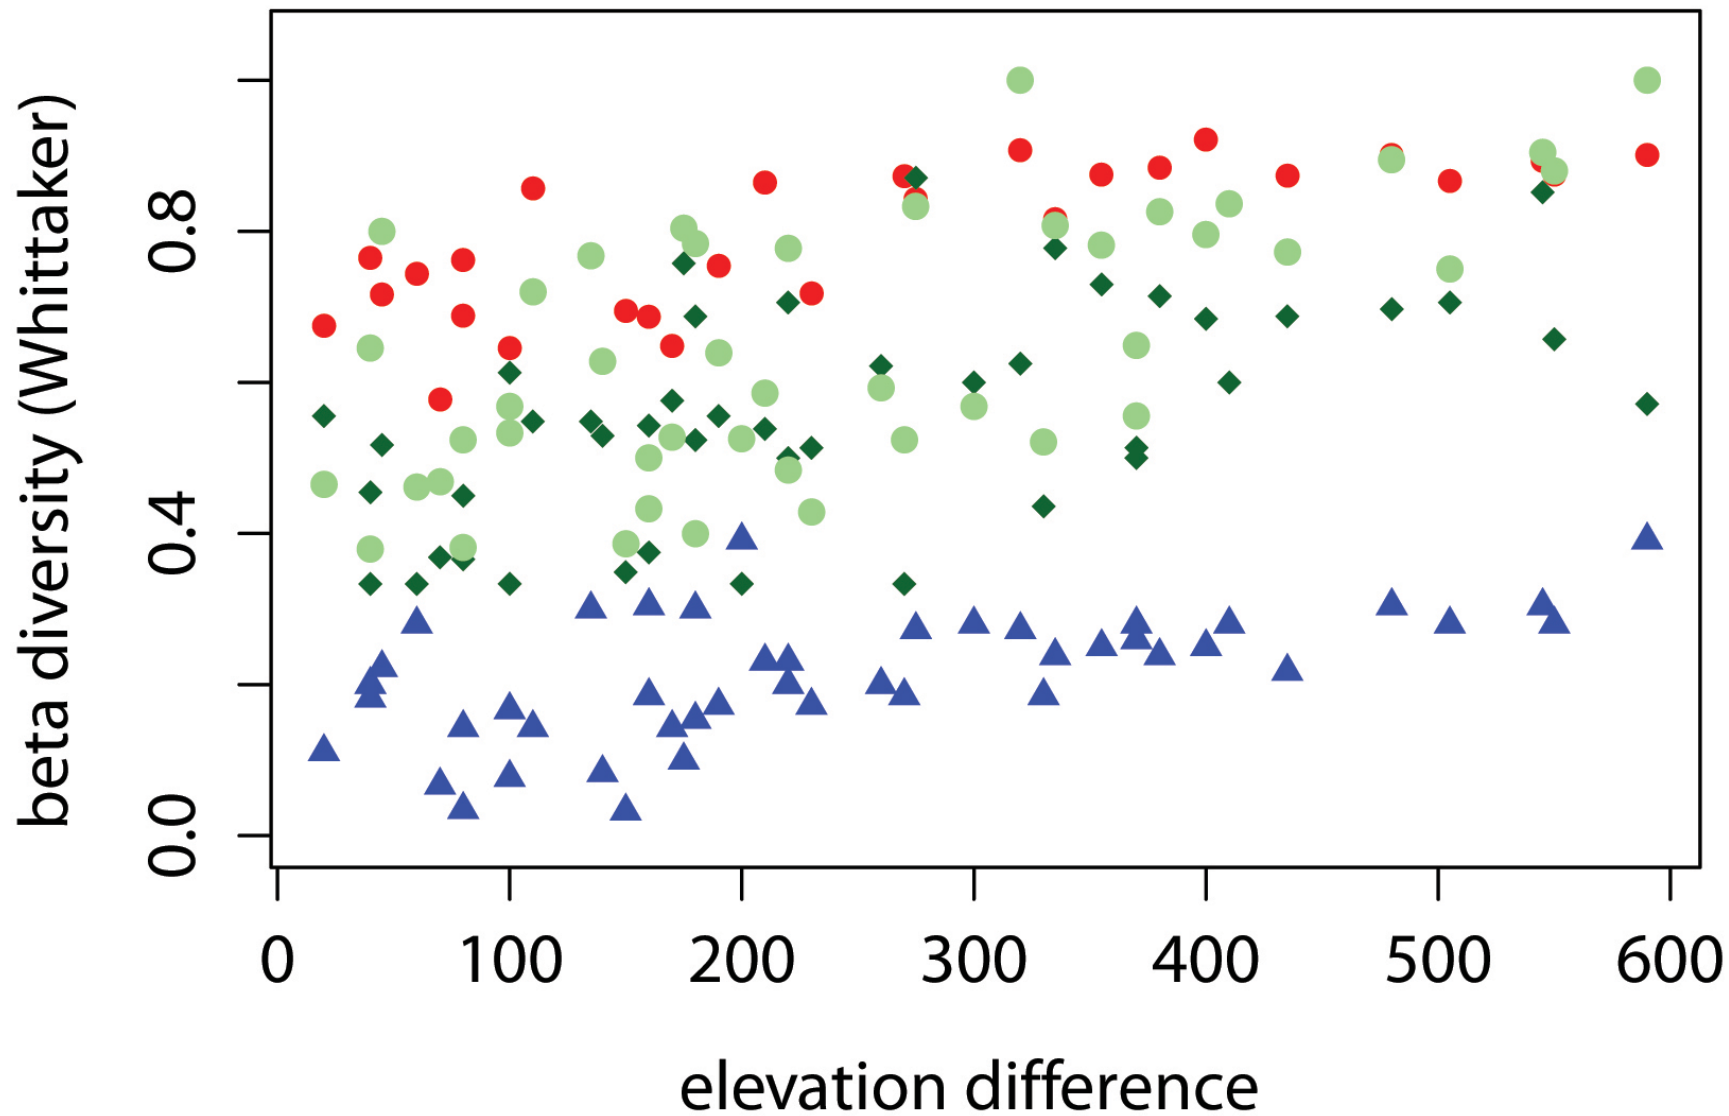

Elevation (m)
Agglomerative Coefficient = 0.44

INVERTEBRATES

Preliminary Conclusions

- Alpha diversity relatively constant across sites
- Beta diversity differences among taxa most likely related to dispersal ability
- Beta diversity differs among sites on the elevational gradient
 - the slope of the relationship is similar for all taxa
- Additional variation in species composition explained by forest structure type

Conservation Value

- Identified that the majority of invertebrate species were unidentified
 - most Genbank hits <80% sequence similarity
- Turn-over rates of biodiversity differ by taxa but respond similarly to our underlying elevation gradient
- Taxa were additionally assorted by other mechanisms (coast, forest type)

The Future

- Refine the sequence pipeline for identifying taxonomic units
- Standardise individual-based measures of detectability across taxa
 - detectability includes sampling and sequencing
- Analyse the data within a theoretical framework such as the Unified Neutral Theory of Biodiversity and Biogeography
